Pilot Zone (PZ) for Renewable Energy Experiments

Bottom Material analysis

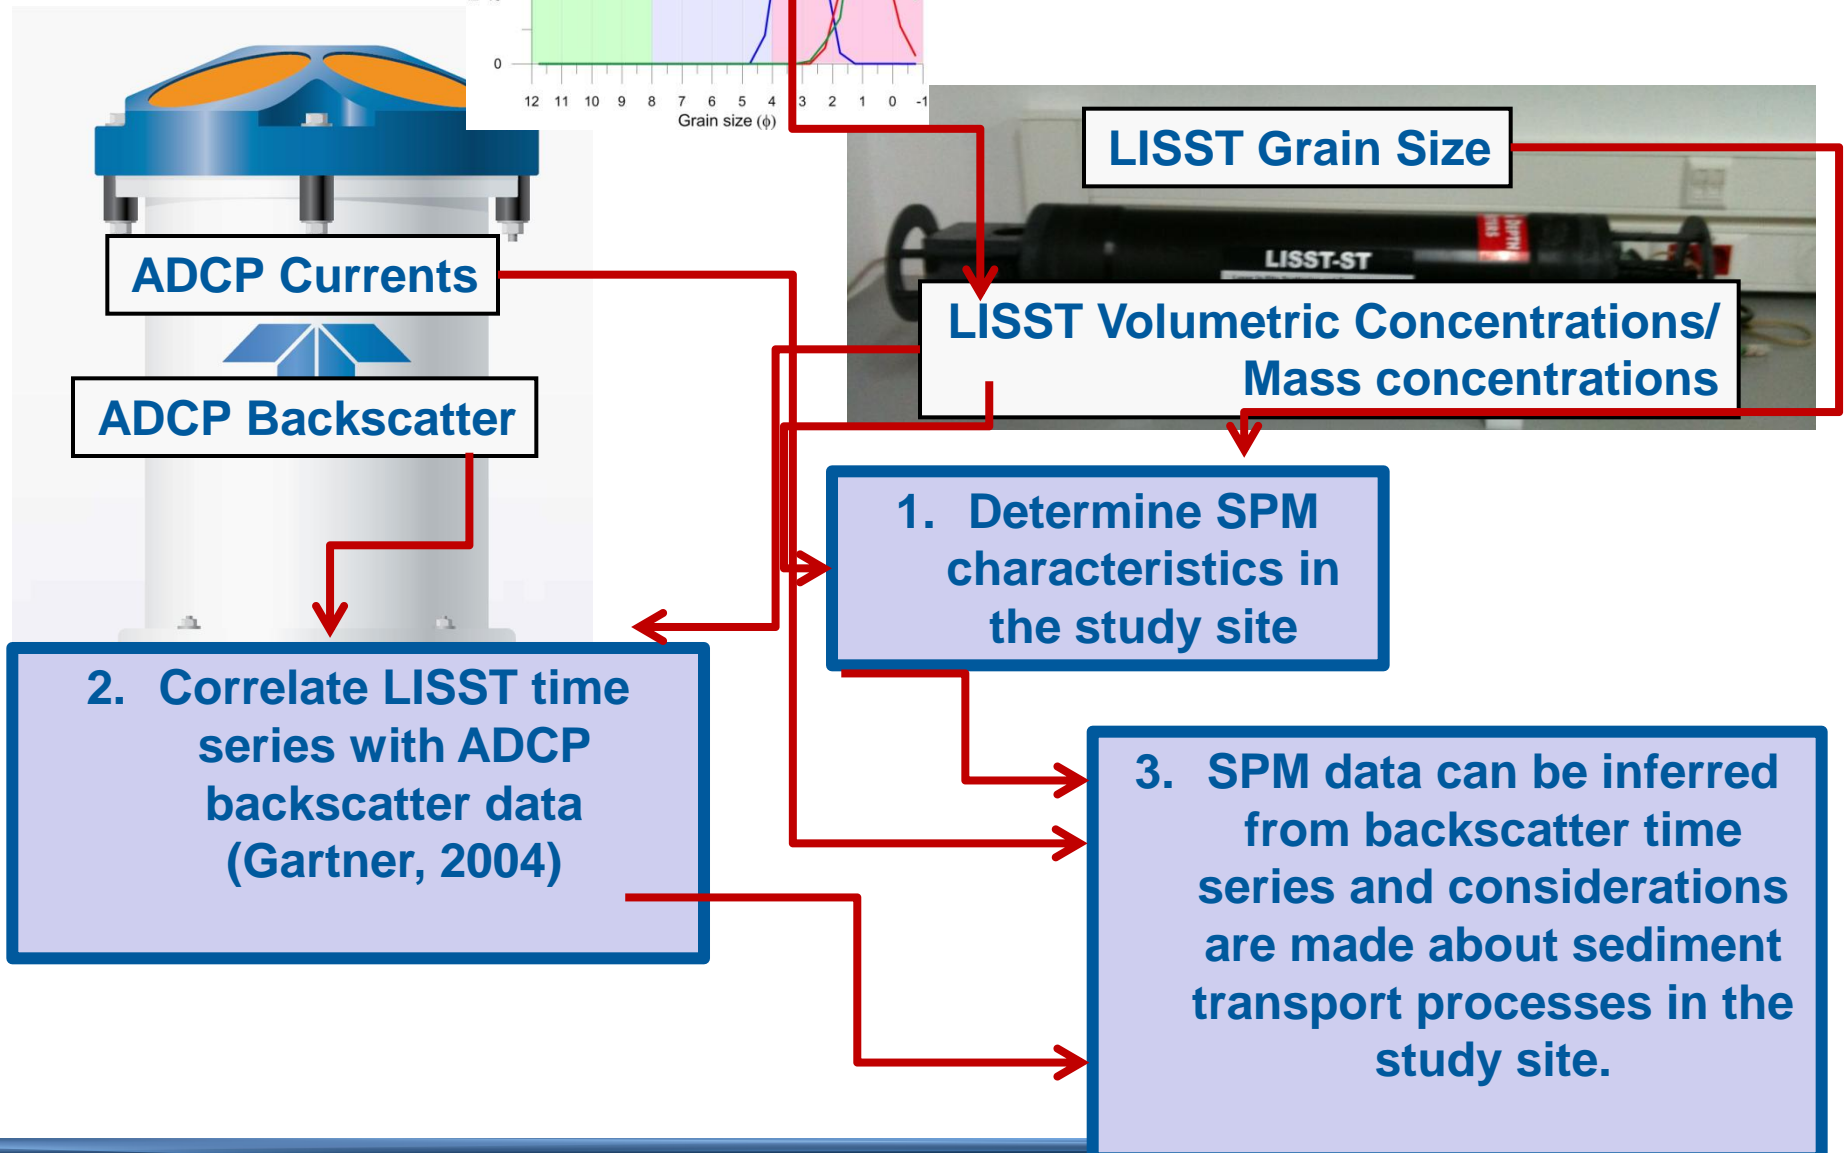

LISST Grain Size

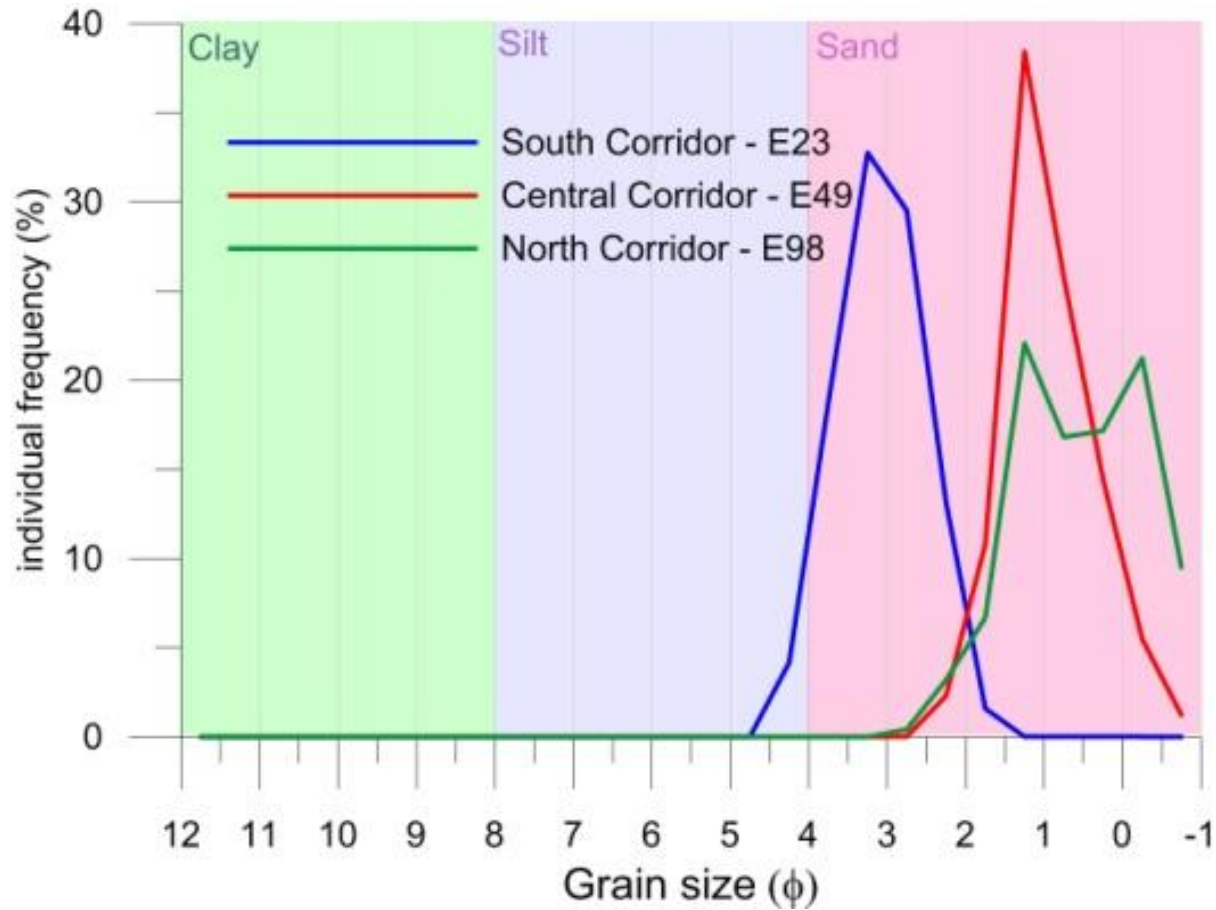

LISST Volumetric Concentrations/ Mass concentrations

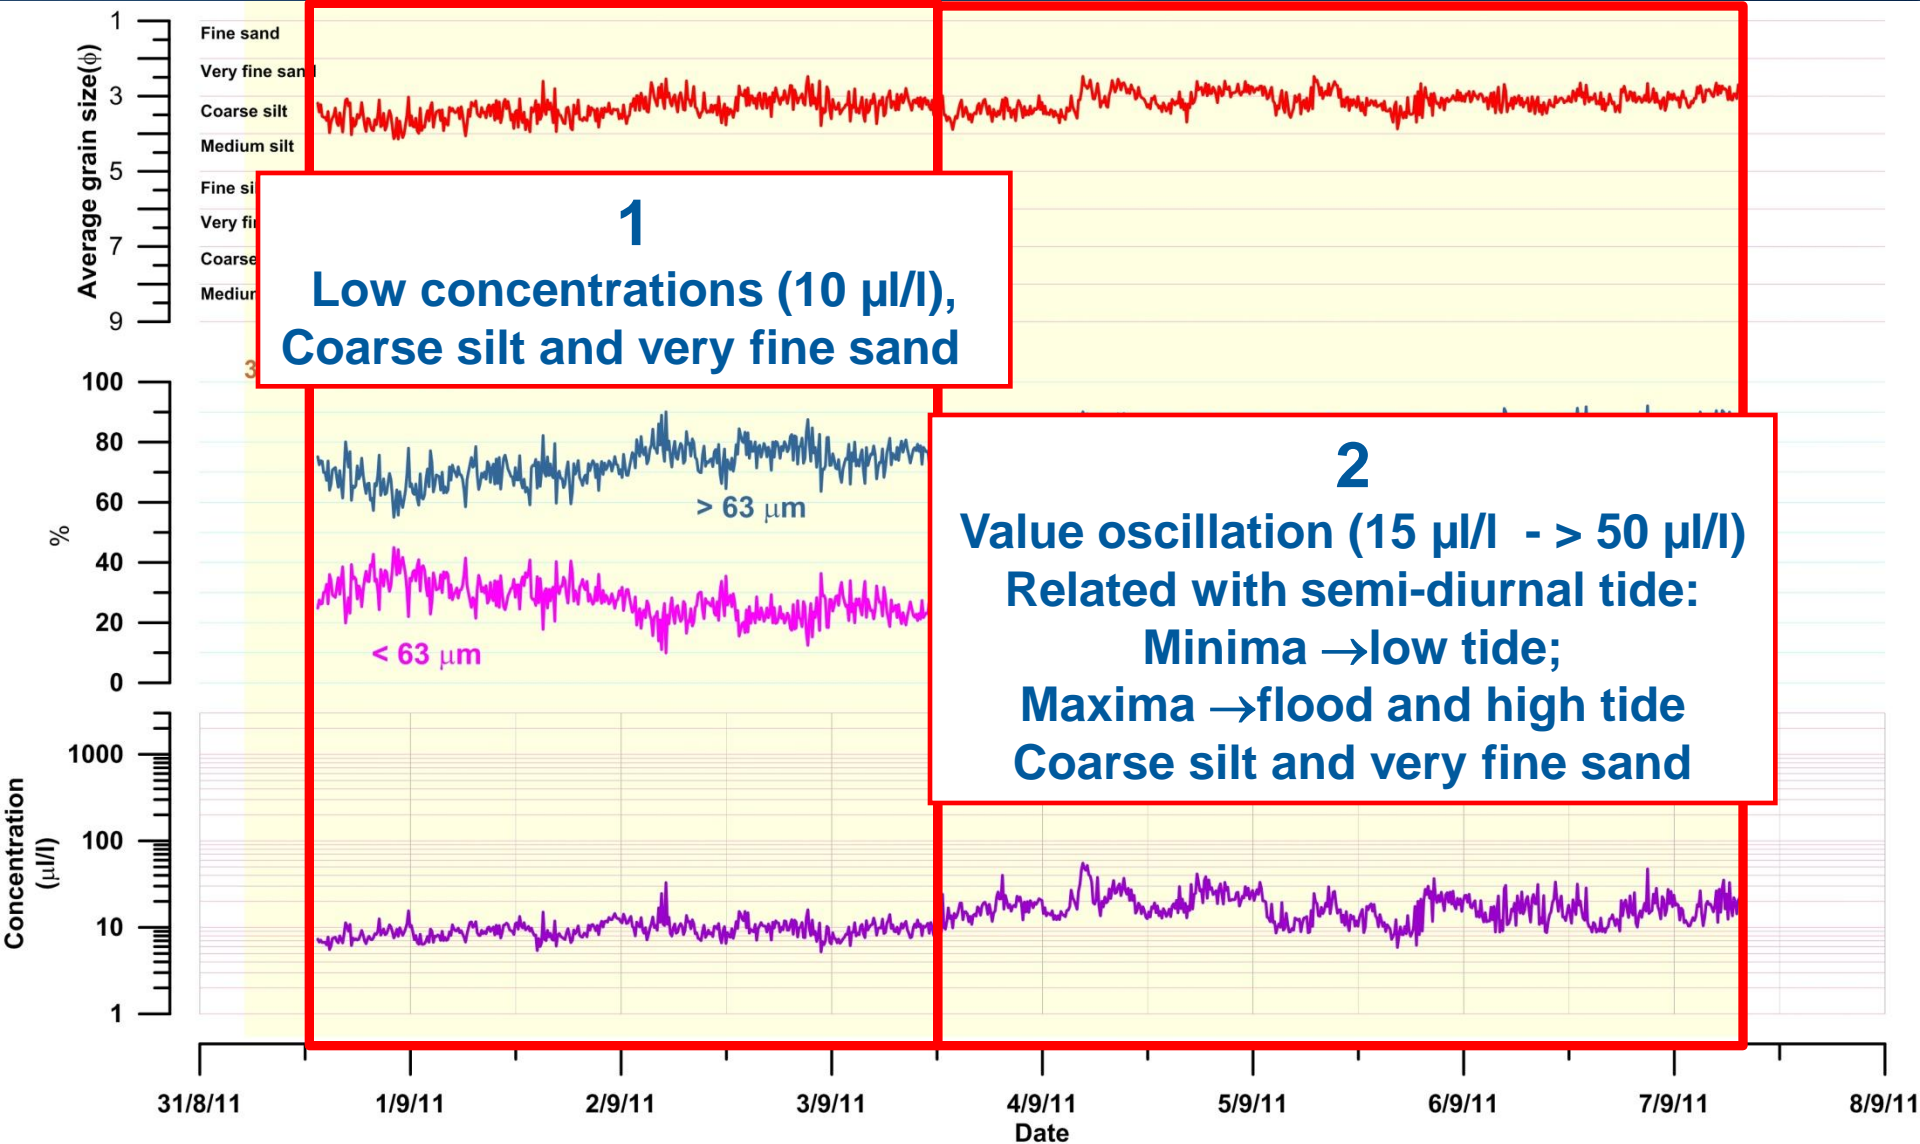

1. Determine SPM characteristics in the study site

2. Correlate LISST time series with ADCP backscatter data (Gartner, 2004)

3. SPM data can be inferred from backscatter time series and considerations are made about sediment transport processes in the study site.

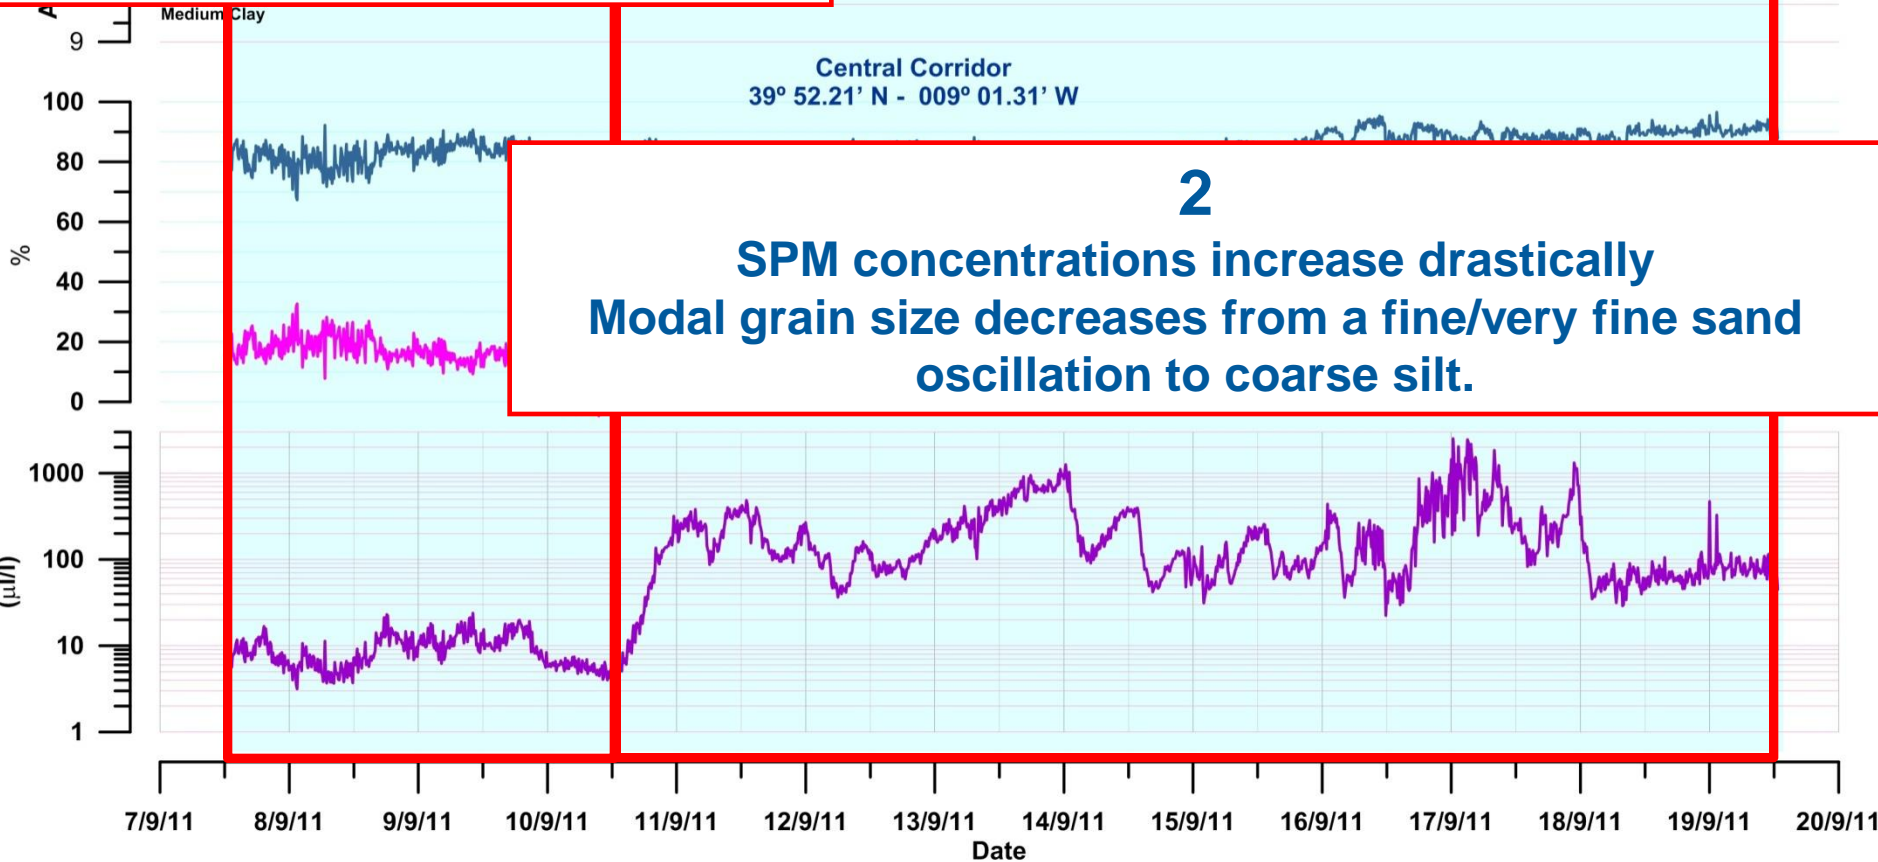

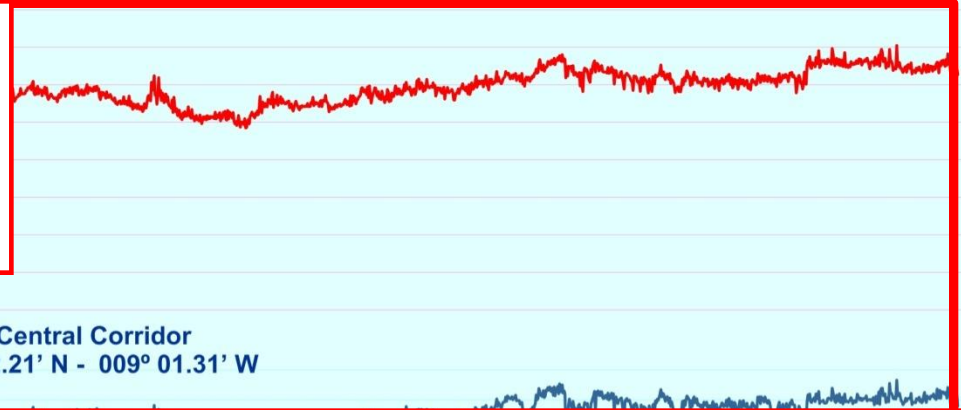

1

Concentration and grain size values are similar to the ones recorded in the south corridor

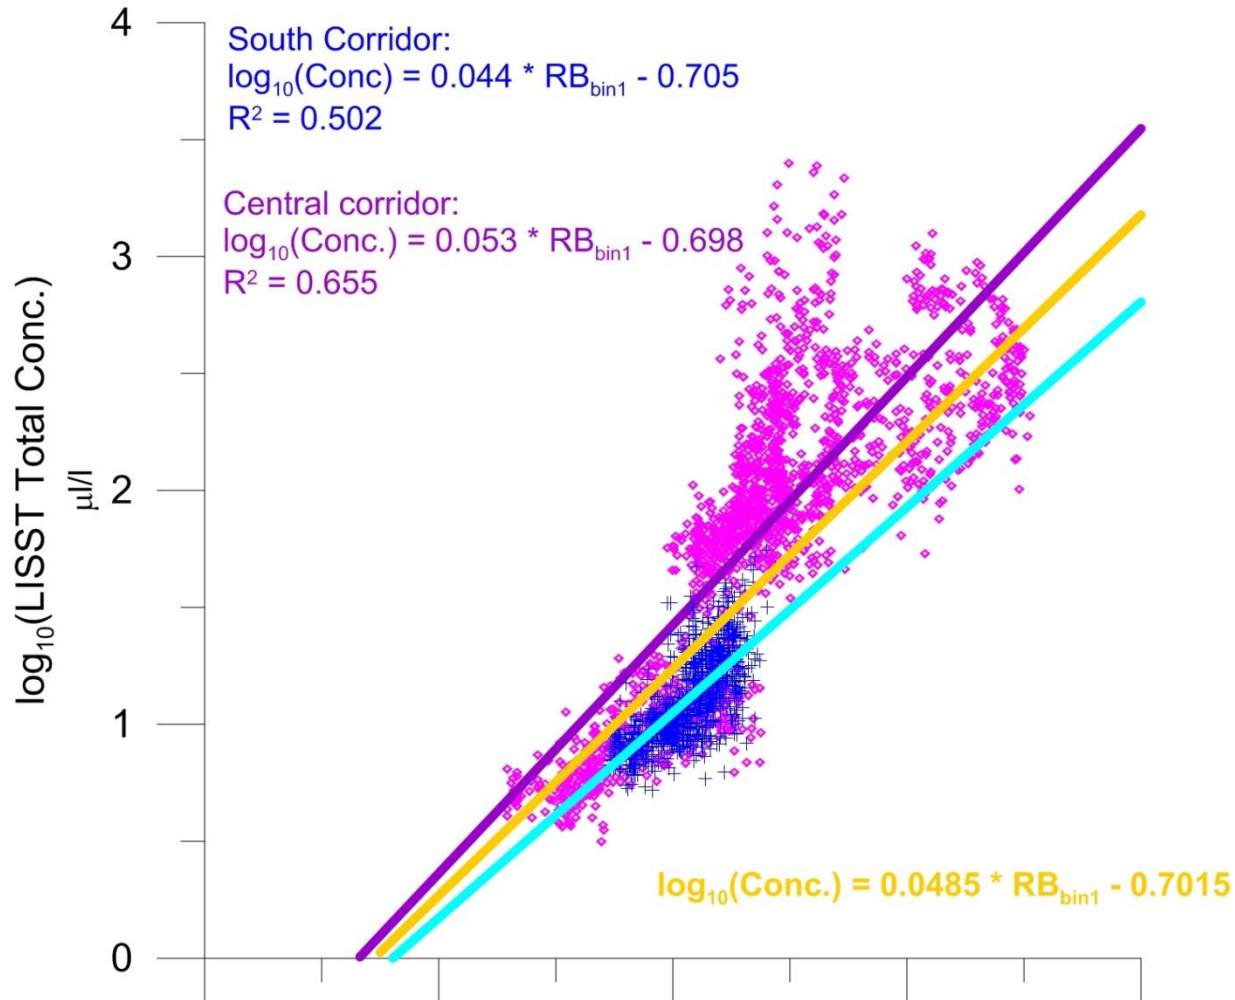

2

SPM concentrations increase drastically
Modal grain size decreases from a fine/very fine sand oscillation to coarse silt.

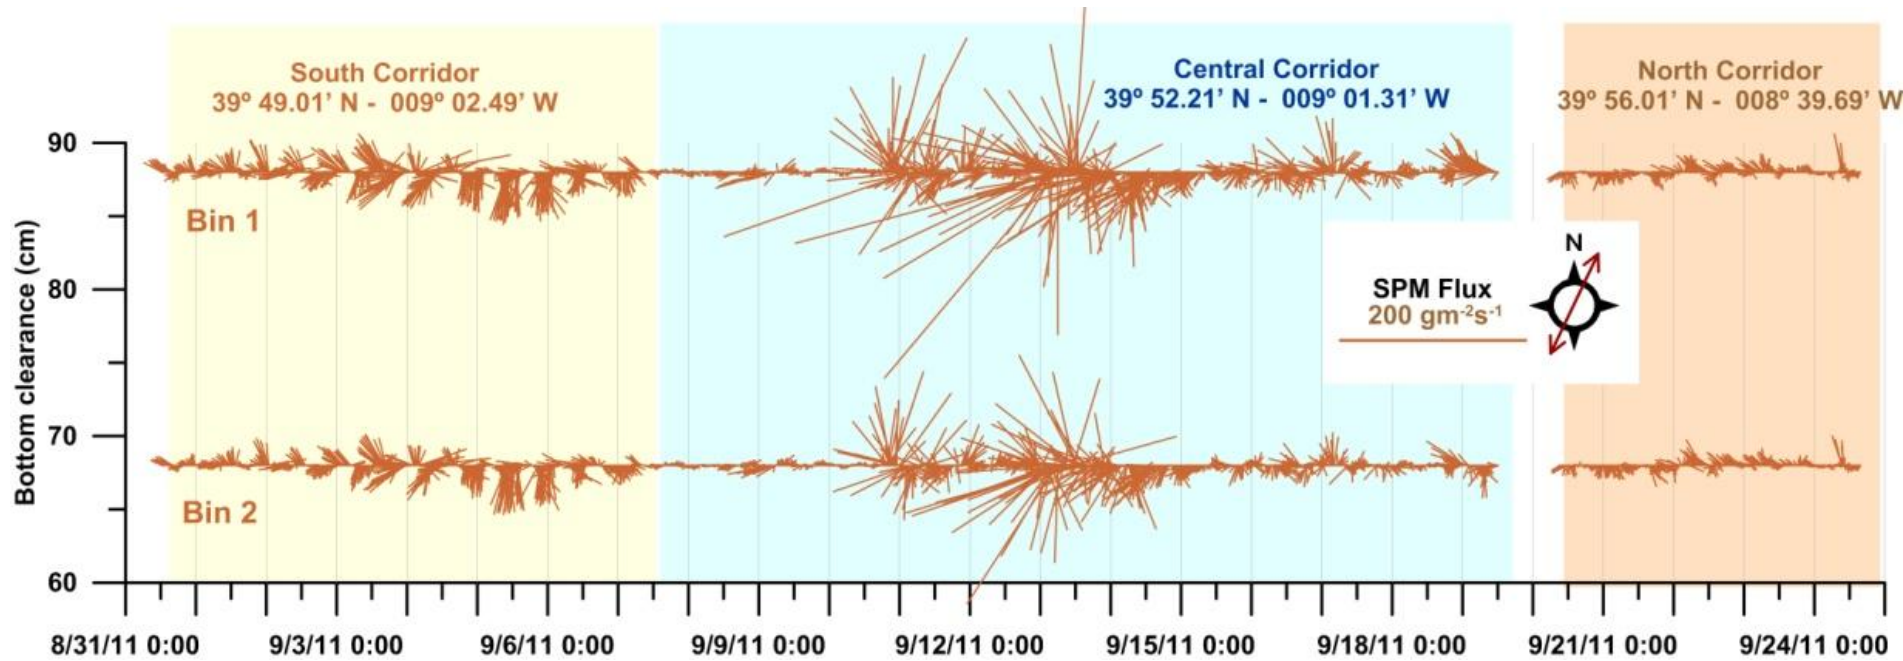

- RB reveal a very close relationship to LISST volumetric concentrations → allow the same conclusions about SPM variations
- In the North corridor RB values are similar to those registered in the southern corridor, even though during this third mooring period the wave regime was significantly more energetic
- In the North corridor no fine sediments were available for resuspension, since bottom sediment cover in this site is coarser than in the previous two sites, and there is no close fluvial discharge

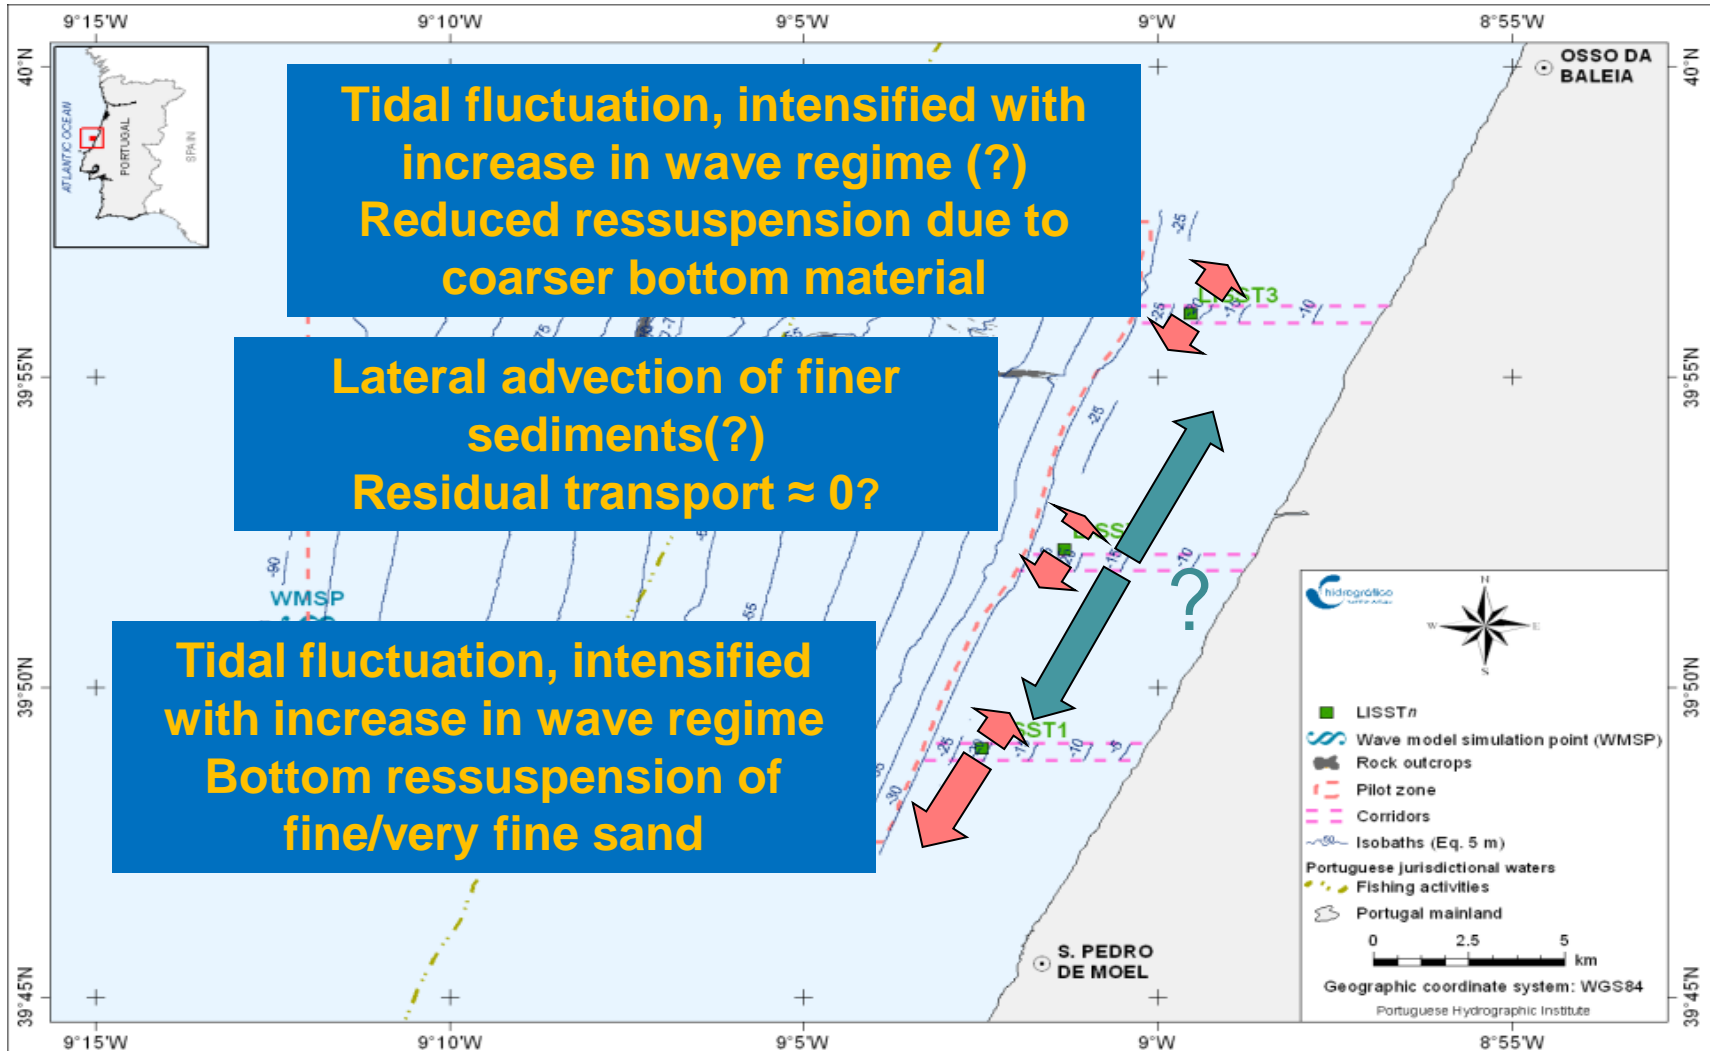

1. Determining the **base line** for ADCP time series (RSSI level);
2. Calculating the **sound absorption factor in the water column** (α - depends both on environmental conditions in the water column as well as on ADCP measurement configuration);
3. Determination of the **transition radius between near and far field** for ADCP transducers (R_{crit});
4. **Distance correction** to the point of measurement for transducer angle;
5. **Two-way transmission loss** calculation, for each of the measuring bins (2TL);
6. **Attenuation loss determination due to SPM concentration** → **this step can be skipped since SPM concentrations measured in this site were about 2 orders of magnitude lower than those used by Gartner in his original study**

$$SPM_{est} = 10^{(0,705+0,0495RB_{bin1})}$$

$$\text{Mass Conc}_{\text{mg/l}} \times \text{Curr}_{\text{mm/s}} \times \vec{\text{Dir}} = \text{SPM Flux}_{\text{g/m}^2\text{s}}$$

This is a contribution to the project “Geophysical characterization of the Pilot Zone for Renewable Energy Experiments” financed by ENEONDAS, Energia das Ondas, S.A.
